

# Lessons V and VI: Overview

1. FX parity conditions
2. Do the PPP and the IRPs (CIRP and UIRP) hold in practice?

# FX parity conditions

# FX parity conditions

---

1. The Law of One Price and the Purchasing Power Parity
2. The Covered Interest Rate Parity (Lesson III)
3. The Uncovered Interest Rate Parity
4. The Fisher-open condition
5. The Forward Rate Unbiased

# The usefulness of parity conditions

---

**Parity conditions** should be thought of as “**break-even values**”, where the decision-maker is indifferent between two available strategies

Parity conditions rely heavily on the “**no free lunch**” principle → violations of parities may give rise to arbitrage opportunities, that would be exploited and reabsorbed in a very short span of time.

# The Law of One Price I

---

*Ceteris paribus*, the price of a product, when converted into a common currency using the spot exchange rate, is the same in every country.

$$P_{iD} = S_{(D / F)} \cdot P_{iF}$$

with  $i = i^{\text{th}}$  product

# Law of One Price II

---

Delving with the *ceteris paribus* condition

There must be no frictions for the LOP to hold, meaning no legal restrictions on the movement of goods, no transportation costs and no tariffs.

# The Purchasing Power Parity I

If the LOP were to hold for a certain basket of goods and services, we get the **Purchasing Power Parity** relation (in **absolute** or **static form**):

$$P_D = S(D / F) \cdot P_F$$

with P = price index of the underlying basket of goods/services

The CIRP applies to financial markets: the PPP can be conceived as a parallel parity condition referring to the products market.

# The Purchasing Power Parity II

Based on the PPP condition, it must be that:

$$S_{PPP} = \frac{P_D}{P_F}$$

1. Whenever  $S_{D/F} > S_{PPP} \rightarrow$  the **domestic currency (D) is undervalued/ the foreign currency (F) is overvalued;**
2. Whenever  $S_{D/F} < S_{PPP} \rightarrow$  the **domestic currency (D) is overvalued/ the foreign currency (F) is undervalued**

# The Purchasing Power Parity III

---

**In practice**, however, it is **difficult** to **test the validity** of PPP in absolute form.

Different baskets of goods are used in different countries to compute price indexes, given that tastes and needs differ on an international scale, affecting what people buy.

# The Purchasing Power Parity IV

Price levels could be substituted with inflation rates

**PPP in relative or dynamic terms**

# Dealing with algebra I

Suppose that at  $t_0$ :

$$P_D = S(D/F) \cdot P_F$$

In 1 year's time, it will be:

$$P_D(1 + \Delta P_D) = S(D/F)(1 + \Delta S_{D/F}) \cdot P_F(1 + \Delta P_F)$$

Divide the latter by the former and get:

$$(1 + \Delta P_D) = (1 + \Delta S_{D/F}) \cdot (1 + \Delta P_F)$$

# Dealing with algebra II

---

Rearranging the terms:

$$\Delta S_{D/F} = \frac{(1 + \Delta P_D)}{(1 + \Delta P_F)} - 1$$

Or, equivalently:

$$\Delta S_{D/F} = \frac{(\Delta P_D - \Delta P_F)}{(1 + \Delta P_F)}$$

# Dealing with algebra III

When inflation is low:

$$\Delta S_{D / F} \cong (\Delta P_D - \Delta P_F)$$

The exchange rate offsets inflation differentials between countries.

## From the PPP to the real FX rate

The real interest rate can be defined as:

$$q_{(D/F)} = \frac{S_{(D/F)} \cdot P_F}{P_D}$$

$q_{(D/F)}$  is a broad summary measure of the prices of one country's goods and services relative to the prices of another's.

# The real exchange rate I

Consider the \$/€ real FX rate

$$q_{(\$ / \text{€})} = \frac{S_{(\$ / \text{€})} \cdot P_{\text{€}}}{P_{\$}}$$

$q_{\$/\text{€}}$  can be conceived as the USD price of European products (goods and services) in terms of American products.

- Whenever  $q_{\$/\text{€}}$  increases/decreases → **real depreciation/appreciation of the USD against the EUR** (i.e. fall/increase of the purchasing power of a \$ within Europe's borders)

# The real exchange rate II

---

$$q_{(\$ / \text{€})} = \frac{S_{(\$ / \text{€})} \cdot P_{\text{€}}}{P_{\$}}$$

If PPP holds, the real exchange rate is perfectly **constant**.

# From the CIRP to the UIRP

---

As long as  $F({}_nD / F) = S^E(D / F)$  (assuming, as usual, risk neutrality and zero transaction costs)...

$$(1 + r_D)^n = \frac{F({}_nD / F)}{S(D / F)} (1 + r_F)^n$$

# The UIRP

$$(1 + r_D)^n = \frac{S^E({}_nD / F)}{S(D / F)} (1 + r_F)^n$$

**Uncovered interest rate parity:** the mathematical expression is almost analogous to the one used for CIRP, apart from the fact that foreign exchange exposure is **not** covered with a forward exchange contract.

# Playing with UIRP I

By definition, it must be that:

$$S^E(D/F) = S(D/F)(1 + \Delta S^E)^n$$

Substituting

$$(1 + r_D)^n = (1 + \Delta S^E)^n \cdot (1 + r_F)^n$$

# Playing with UIRP II

Taking the  $n^{\text{th}}$ -root and multiplying yield

$$1 + r_D = 1 + \Delta S^E + \Delta S^E \cdot r_F + r_F$$

If we ignore interaction terms, we will get

$$\Delta S^E = r_D - r_F$$

Higher-yield currencies are expected to depreciate

# Combining PPP and UIRP

---

If we combine

$$\Delta S^E = r_D - r_F$$

and

$$\Delta S^E = \Delta P^E_D - \Delta P^E_F$$

we get

$$r_D - \Delta P^E_D = r_F - \Delta P^E_F$$

# The Fisher-open condition

$$r_D - \Delta P^E_D = r_F - \Delta P^E_F$$

**Fisher-open condition:** real interest rates are equal in different countries.

**High-yield currencies** carry more **inflation risk** and tend to **depreciate** over time

# UIRP, PPP and Fisher-open condition

# The Fwd Rate Unbiased

If  $F({}_nD / F) = S^E(D / F)$ , we could infer that

$$\frac{F({}_nD / F) - S_t}{S_t} = \frac{S^E(D / F) - S_t}{S_t}$$

Today's fwd premium/discount  
equals...

...the expected percentage change  
in the spot rate

---

Do the PPP and the IRPs (CIRP and UIRP) hold in practice?

# Does PPP hold in practice?

---

Testing the validity of PPP may be troublesome as a consequence of:

- 1. Different baskets of goods** underlying the price index;
- 2. Non tradable goods;**
- 3. Transaction costs** (quotas, tariffs, duties);
- 4. Different consumers' preferences** → **Different price indexes' weighting schemes;**
- 5. Oligopolistic markets**

# Statistical evidence I

The emerging empirical evidence suggests that:

- **PPP performs poorly in the short run;**
- Prices seem to revert to their PPP levels in the long run → **mean reverting processes;**
- **The speed of adjustment** towards the PPP level is a **positive function of the size of the deviation;**
- **PPP deviations may be permanent** if a permanent **real shock** affects one country but not the other

# Statistical evidence II

High productivity gains

Higher real income growth

Appreciating real exchange rates

Non constant real exchange rates

# Balassa-Samuelson effect I

The PPP states that, when expressed in terms of a single currency, countries' price levels should approximately equate.

The empirical evidence, however, suggests that countries' price levels are positively related to (per capita) real income dynamics (i.e. prices tend to be higher in richer countries)

**Balassa-Samuelson effect**

# Balassa-Samuelson effect II

**Poor countries**: the labor force is less productive in the tradables sector (whilst international productivity differences in nontradables are negligible) → lower productivity implies lower wages, which further imply lower production costs and, consequently, lower price levels.

The Balassa-Samuelson effect can help explain (apparent) persistent deviations from PPP

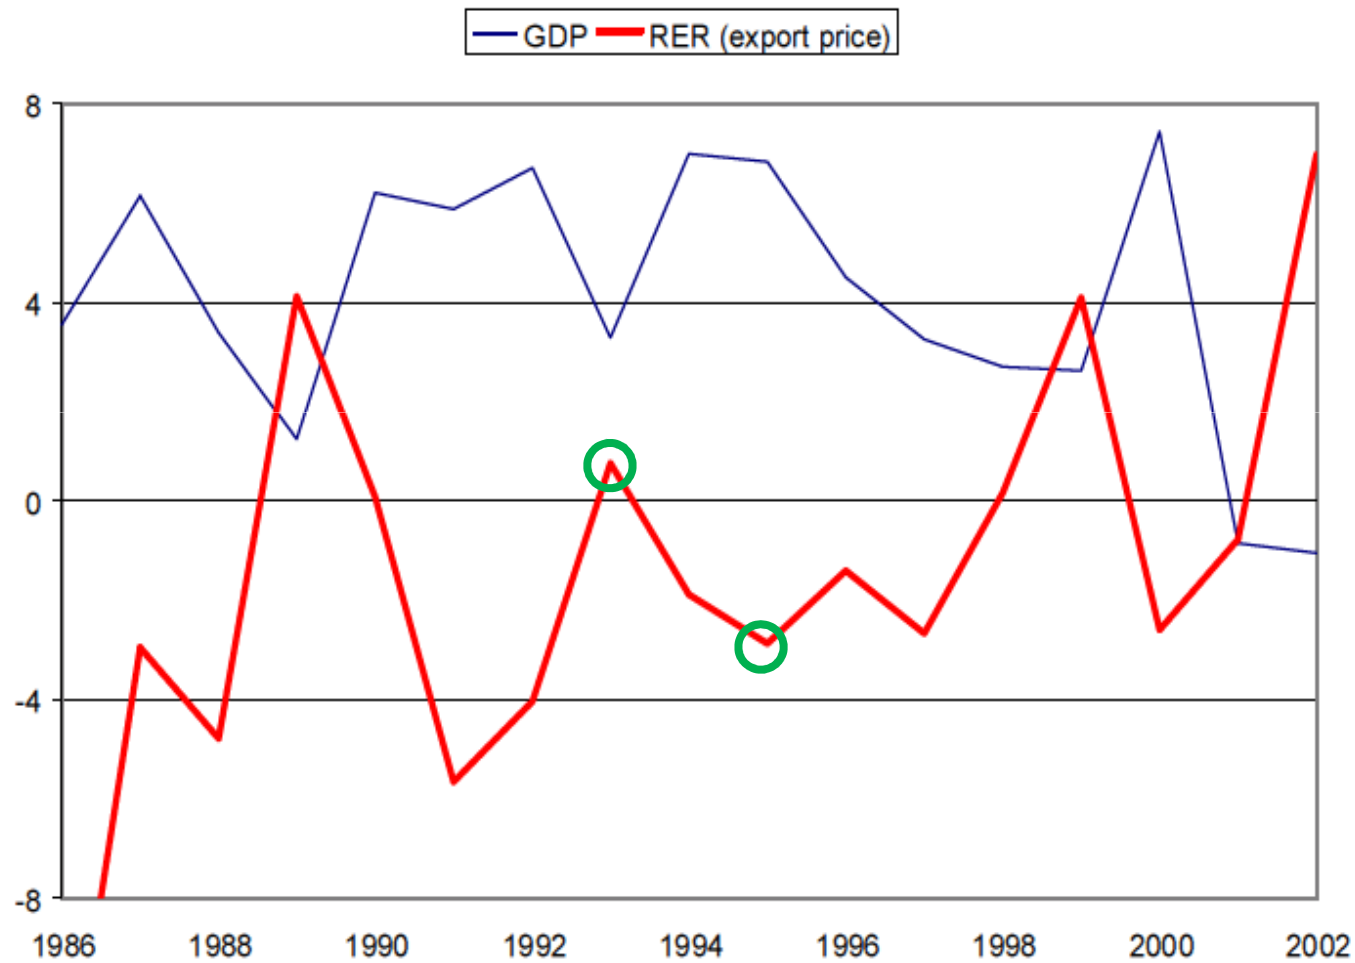

# Balassa-Samuelson effect III

**ALP:** Avg labor productivity

**TFP:** Total factors productivity

# Balassa-Samuelson effect IV

**RER** ₪/\$: Real Exchange Rate

Source: Central Bank of Israel

# Does CIRP hold in practice?

---

**Very closely, but not exactly** as a consequence of:

- 1. Execution risk**
- 2. Transaction costs (Is it really so?...)**
- 3. Political risk**
- 4. Tax advantages**
- 5. Liquidity differences**

# The CIRP and the execution risk

There might be time lags during execution, thus implying some extra risk → placing orders takes time and market prices may change

This tends to create a “band” around the CIRP line

# The CIRP and the transaction costs

Transaction costs do **not always** contribute to deviations from IRP

Round-trip arbitrages tend to create a “band” around the CIRP line, whilst one-way arbitrages do not (Lesson III)

# The CIRP & the political risk I

Political risk involves the uncertainty that while funds are invested in a foreign country, they may be frozen (they cannot be repatriated), confiscated or even made inconvertible into other currencies.

Investors typically require a risk premium from foreign investments versus domestic investments

# The CIRP & the political risk II

Political risk creates a “band” around the CIRP line.

The band does not have to be of equal width on the two sides of the CIRP line, if one country is seen as riskier than the other.

# The CIRP and tax dynamics

As long as tax rates depend on the country in which funds are borrowed/invested, the interest parity condition will be affected.

Two ways in which taxes can affect the parity condition:

- 1. Withholding taxes;**
- 2. Differences** between the tax rate on income ( $\tau_I$ ) and the tax rate on capital gains ( $\tau_K$ )

# Withholding tax

Withholding tax: tax applied to foreigners at the source of their earnings.

Withholding taxes are unlikely to create any “band” around the parity line “**iff**” the **rate of withholding**  $\leq$  the tax **rate** that would be **applied to the earnings at home**, since domestic withholding tax credits (purposely designed to avoid double taxation) will offset the tax withheld.

# Income vs K gains taxation I

$$r_{\$} - r_{\pounds} = \frac{1 - \tau_K}{1 - \tau_I} n \left[ \frac{F \frac{1}{n} \$ / \pounds - S_{\$ / \pounds}}{S_{\$ / \pounds}} \right]$$

As long as  $\tau_K < \tau_I$ ,

$$\frac{1 - \tau_K}{1 - \tau_I} > 1$$

Investors (borrowers) with favorable capital gains treatment will prefer investments denominated in currencies trading at a forward premium (discount)

# Income vs K gains taxation II

If  $\tau_{\text{Capital Gains}} \neq \tau_{\text{Interest Income}}$ , the slope of the CIRP line may be affected.

After taxes, if capital gains taxes are paid on foreign exchange earnings, even when hedged, the investor will receive only  $(1 - \tau_{\text{Interest Income}})$  of the interest and  $(1 - \tau_{\text{Capital Gains}})$  of the gain from the forward premium (considered as a K gain)

# The CIRP & liquidity differences I

**Liquidity** refers to **how easily, quickly and cheaply** an asset can be converted into cash.

Suppose the funds put in a covered foreign investments are needed earlier → the investor might incur in potential losses when monetizing the original investment

# The CIRP & liquidity differences II

Liquidity preference is likely to create a **band** around the **covered interest-parity line**.

The potential width of the band due to liquidity preference depends on the likelihood that the funds will be needed earlier.

# Does the CIRP hold in practice?

---

Empirically, the CIRP seems to hold:

- in the eurocurrency market;
- for short term lending/borrowing.

# Statistical evidence on UIRP

---

The empirical evidence reveals that the **UIRP holds poorly in the short run.**

- Whenever short term interest rates are high, currencies tend to appreciate;
- “Carry trade” strategies are profitable in the short run;
- Basket carry trade strategies perform even better

## Carry trade

Trading strategy consisting in selling a relatively low interest rate currency and using the funds to purchase another yielding a higher interest rate.

## Explosive growth in DEBT/GDP ratios

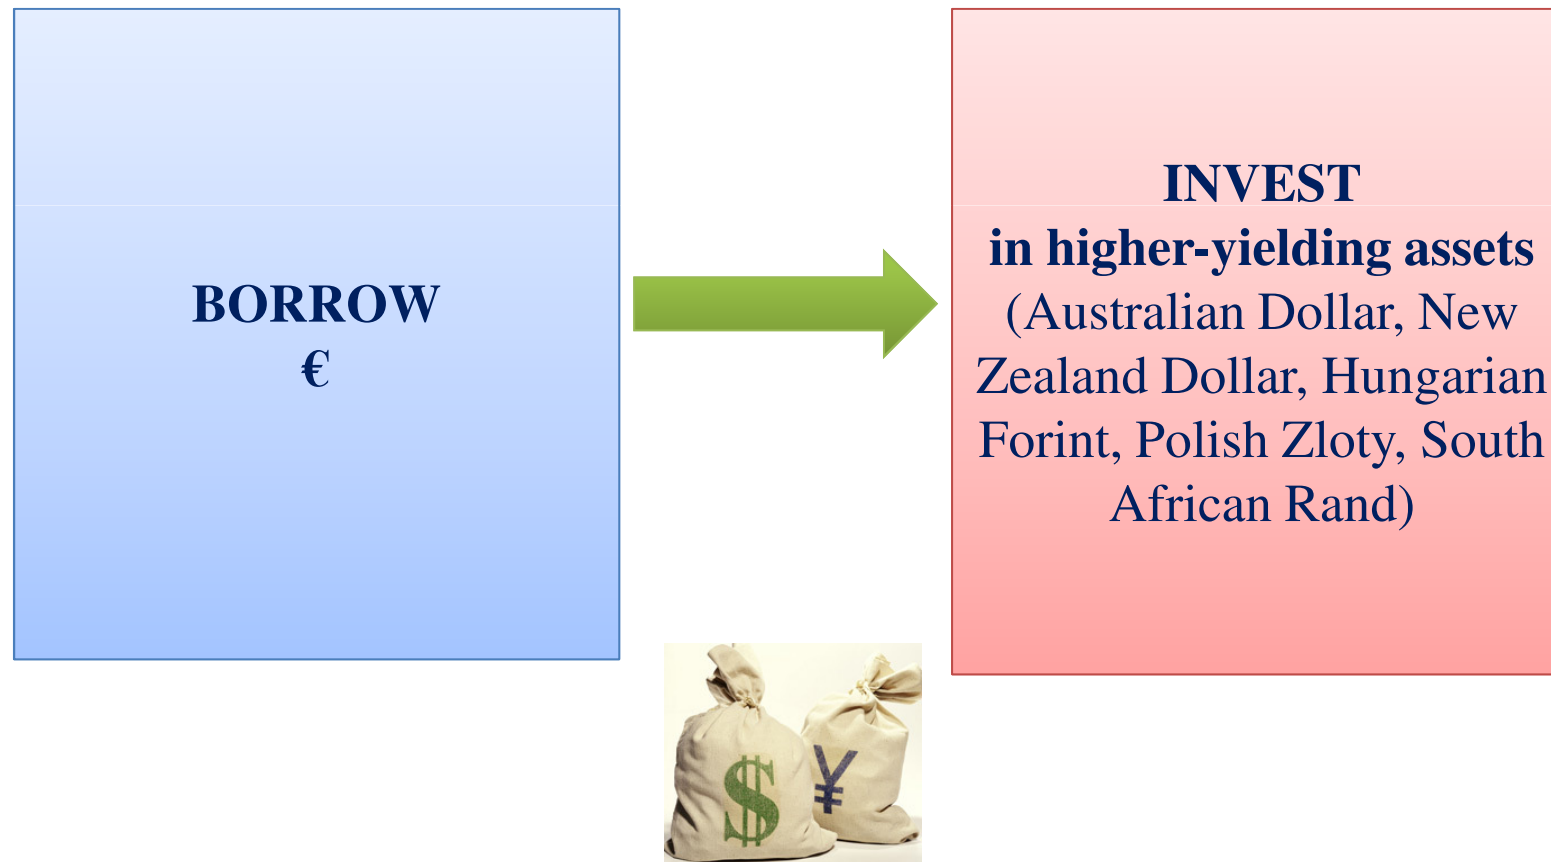

# Carry Trade in practice (Q<sub>2</sub>-2012) IV

As if it were not enough...

# Carry Trade in practice (Q<sub>2</sub>-2012) V

The **Euro** started to be conceived as a **funding currency**

## Speculative bet against the Euro

26<sup>th</sup> July 2012: *“Within our mandate, the ECB is ready to do whatever it takes to preserve the Euro. And believe me, it will be enough”.*

# To put it into practice I

You have been given the following information:

$r_{\$}$	$r_{\pounds}$	$S_{(\$/\pounds)}$	$F_{(\$/\pounds)}$
5%	6%	1.5	1.4895

where

$r_{\$}$  = annual interest rate on US-dollar short term paper

$r_{\pounds}$  = annual interest on British-pound short term paper

On the basis of the foregoing data:

- In which paper would you invest?
- In which currency would you borrow?
- How would you arbitrage?
- What is the profit from interest arbitrage per dollar borrowed?

# To put it into practice III

---

Based on the LoP and considering the table above...

1. Which is the most overvalued currency?  
Why?

2. Which is the most undervalued currency?  
Why?
