

- 1. The relationship between spot, forward and money market rates
- 2. How to construct synthetic securities

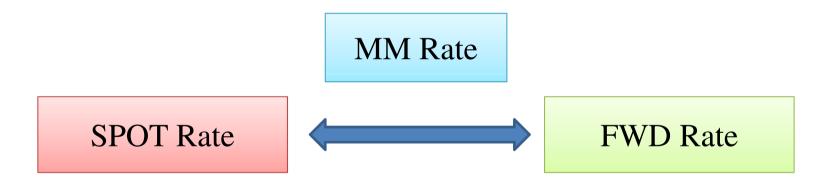

The relationship between spot, forward and money rates

Spot, Fwd & MM Rates

Investment/borrowing decisions and currencies of denomination I

Assume you have some funds to place in the money market for 3 months: how to choose between domestic and foreign currency-denominated securities?

Relying exclusively on interest rate differentials might be seriously misleading: both **interest and exchange rates** should be taken into due account.

Investment/borrowing decisions and currencies of denomination II

<u>1st option</u>: invest in a USD-denominated security (assuming \$ is the domestic currency)

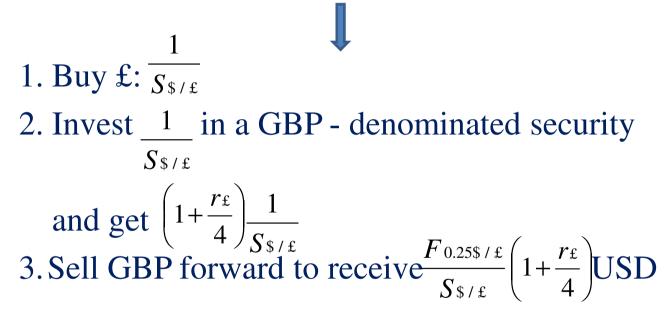

At the end of a 3 months period, this would yield

$$\left(1+\frac{rs}{4}\right)$$

Investment/borrowing decisions and currencies of denomination III

<u> 2^{nd} option</u>: buy £ to invest in a GBP-denominated security and finally sell GBP foward after 3 months

Investment/borrowing decisions and currencies of denomination IV

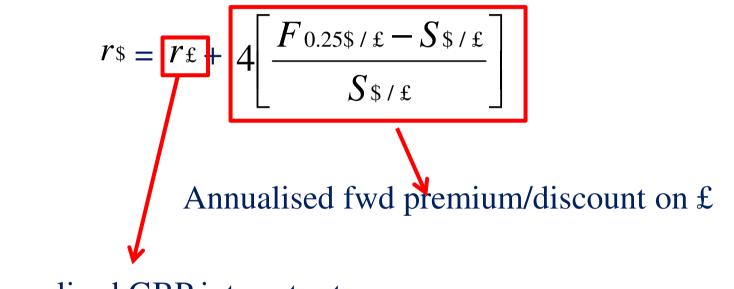

You will be indifferent between the two options only if

$$\left(1+\frac{r_{\$}}{4}\right) = \frac{F_{0.25\$/\pounds}}{S\$/\pounds} \left(1+\frac{r_{\pounds}}{4}\right)$$

Investment/borrowing decisions and currencies of denomination V

Rearranging the terms we would get:

Annualised GBP interest rate

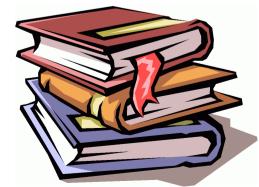

More generally, if we allow for compound interest, an investor/ borrower would be indifferent between domestic and foreign currency denominations of investment or debt if

$$(1+r_D)^n = \frac{F({}_{nD}/F)}{S({}_{D}/F)}(1+r_F)^n$$

When steps have been taken to avoid foreign exchange risk by use of forward contracts (hence the term "covered"), rates of return on investments and costs of borrowing will be equal, irrespective of the currency of denomination (*ceteris paribus*)

Covered Interest Rate Parity III

Delving with the *ceteris paribus* condition

There must be no frictions for the CIRP to hold, meaning no legal restrictions on the movement of K, no tax advantages among different countries...

The CIRP links tightly together Spot and Forward rates \rightarrow persistent deviations are **unlikely** to occur, because this would give rise to arbitrage opportunities (<u>No Free Lunch</u> <u>Principle</u>)

Deviations & arbitrage opportunities I LIUC

Suppose that

$$(1+r_D)^n < \frac{F(nD/F)}{S(D/F)}(1+r_F)^n$$

The best thing to do would be to **borrow in your domestic currency** and to **invest simultaneously in a foreign currency-denominated security.** At the end of the investment period, the hedged transaction will allow you to get more than required to repay the initial debt (i.e. you will receive more domestic currency)

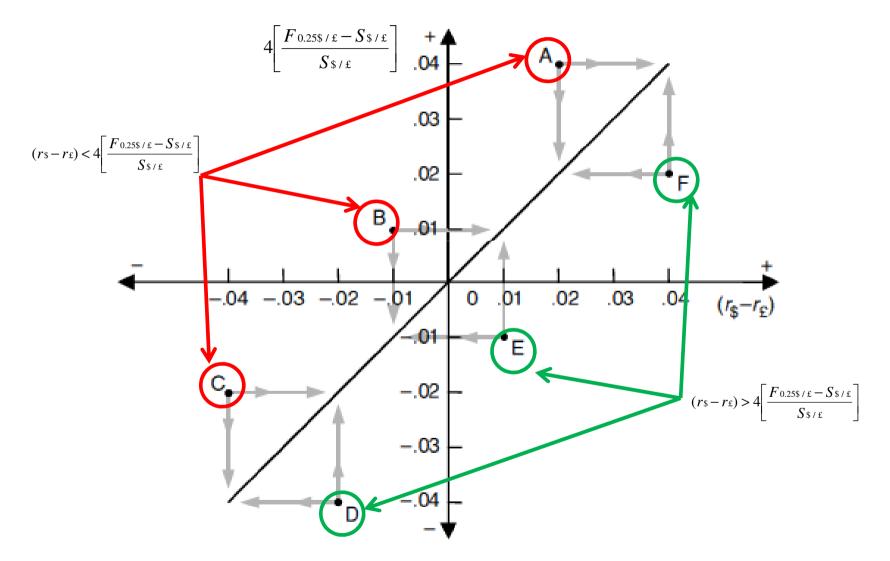

Deviations & arbitrage opportunities II LIUC

What if

$$(1+r_D)^n > \frac{F({}_{nD}/F)}{S({}_{D}/F)}(1+r_F)^n$$

The best thing to do would be to **borrow foreign currency** and to **invest simultaneously in a domestic currency-denominated security**. At the end of the investment period, the hedged transaction will allow you to get more than required to repay the initial debt

15

For all the points lying above the 45°line (A,B and C), it must be that

$$(r_{f}-r_{f}) < 4 \cdot \left[\frac{F_{0.25f}/f}{S_{f}}\right]$$

This further implies:

- Covered investment in £ yields more than in \$;
- Borrowing in \$ is cheaper than covered borrowing in £

The adjustment procedure driving A, B, and C down towards the 45° line works as follows:

- 1. Borrow \$, thus tending to increase $r_{\$}$;
- 2. Buy spot £ with the borrowed \$, thus tending to increase $S_{(\$/\pounds)}$;
- 3. Buy a £ security, thus tending to reduce r_{f} ;
- 4. Sell the £ investment proceeds forward for \$, thus tending to reduce $F_{0.25 \, (\$/\pounds)}$.

Points 1 to 4 will all push **A**, **B** and **C** back down to the CIRP line

For all the points lying below the 45°line (D, E and F), it must be that

$$(r_{\$}-r_{\pounds}) > 4 \left[\frac{F_{0.2\$/\pounds}-S_{\$/\pounds}}{S_{\$/\pounds}} \right]$$

This further implies:

- Covered investment in \$ yields more than in £;
- Borrowing in £ is cheaper than covered borrowing in \$

The adjustment procedure driving D, E, and F up towards the 45° line works as follows:

- 1. Borrow £, thus tending to increase r£;
- Buy spot \$ with the borrowed £, thus tending to decrease S(\$/£);
- 3. Buy a \$ security, thus tending to reduce r\$;
- 4. Sell the \$ investment proceeds forward for £, thus tending to increase F0.25 (\$/£).

Points 1 to 5 will all push **D**, **E** and **F** back up to the CIRP line

Don't forget transaction costs I

Covered investment/borrowing involve two FX transactions (one on the spot market and the other on the forward market)

Transaction costs have to be borne twice

There could be deviations from interest rate parity due to the extra transaction costs of investing/borrowing in foreign currency...

Is it always so?

Don't forget transaction costs II

It can be shown that transaction costs do <u>not always</u> contribute to deviations from CIRP.

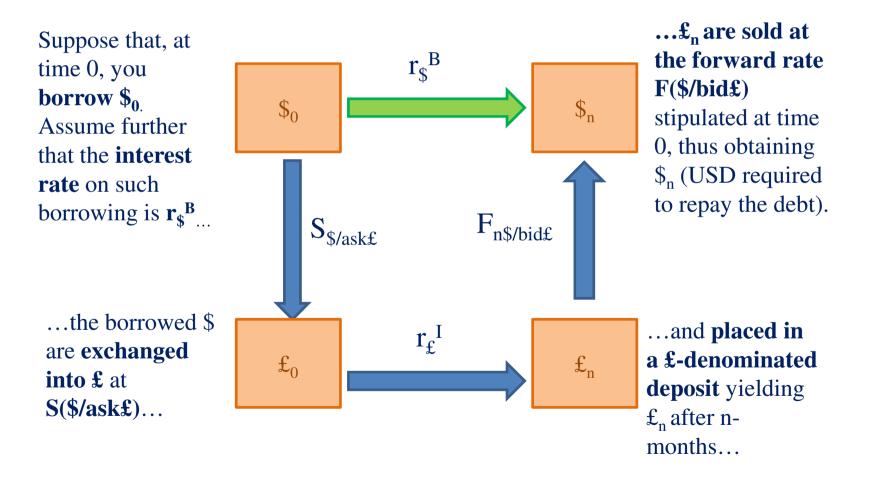

Some preliminary notation:

- S(\$/ask£), S(\$/bid£) = spot exchange rate when buying/selling £ with \$ respectively
- F_n(\$/ask£), F_n(\$/bid£) = n-year forward exchange rate when buying/selling £ with \$
- $r_{\$}{}^{\rm I}$ and $r_{{\bf \pounds}}{}^{\rm I}$ = interest rates earned on USD/GBP-denominated investments
- $\mathbf{r}_{\B and \mathbf{r}_{\pounds}^{B} = interest rates due on USD/GBP-denominated borrowings

Don't forget transaction costs III

Case a) round-trip covered interest rate transaction

Based on the CIRP, we could write

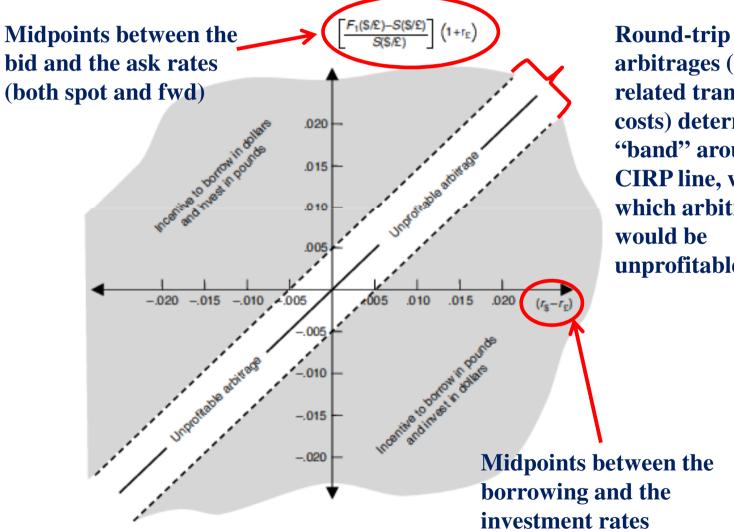

$$(1+r\mathfrak{s}^{B})^{n} = \frac{F_{n}(\mathfrak{s}/\operatorname{bid}\mathfrak{t})}{S(\mathfrak{s}/\operatorname{ask}\mathfrak{t})}(1+r\mathfrak{t}^{I})^{n}$$

This is <u>NOT</u> a perfect 45° -line on the CIRP diagram, but more a "band" drawn around mid-rates. This is because of the transactions costs to be borne:

- Bid-ask spread = $(S(\$/ask \pounds) F_n(\$/bid \pounds))$
- Borrowing-investment transaction costs = $(r_{\$}^{B} r_{t}^{I})$

Don't forget transaction costs V

arbitrages (and the related transaction costs) determine a "band" around the **CIRP** line, within which arbitrages unprofitable

24

Don't forget transaction costs VI

Case b) one-way covered interest rate transaction

 $r_{\I If you need \pounds_n ... or invest \$₀ in a sometime in the \$_n **\$**₀ **\$-denominated** future and you have \$₀ today, you deposit and use the proceeds $(\$_n)$ to could either... buy £ forward at F_{n\$/ask£} S_{\$/ask£} **F**_n(**\$/ask£**), when GBP are needed.sell \$ for £ on the spot mkt at $r_{\rm f}^{\rm I}$ S(\$/ask£) and **invest** them in a **£**- \mathbf{f}_0 \mathfrak{L}_n denominated **deposit** yielding \pounds_n

when GBP are

needed.

Don't forget transaction costs VII

Based on the CIRP condition, we could write

$$(1+r\mathfrak{s}^{I})^{n} = \frac{F_{n}(\mathfrak{s}/\mathfrak{ask}\mathfrak{t})}{S(\mathfrak{s}/\mathfrak{ask}\mathfrak{t})}(1+r\mathfrak{t}^{I})^{n}$$

This would plot an exact 45° line in the CIRP diagram, given that there are virtually no transaction costs:

- Bid-ask spread = $(S(\$/ask \pounds) F_n(\$/ask \pounds))$
- Borrowing-investment transaction costs = $(r_{\underline{s}}^{I} r_{\underline{t}}^{I})$

To sum up I

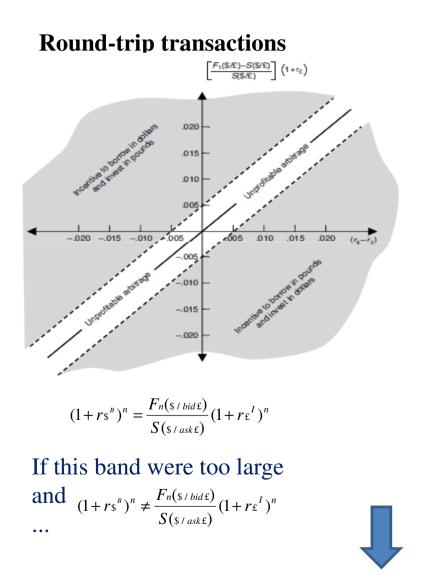

For round-trip arbitrages to be profitable, deviations from the CIRP line must be large enough to overcome **transaction costs...**

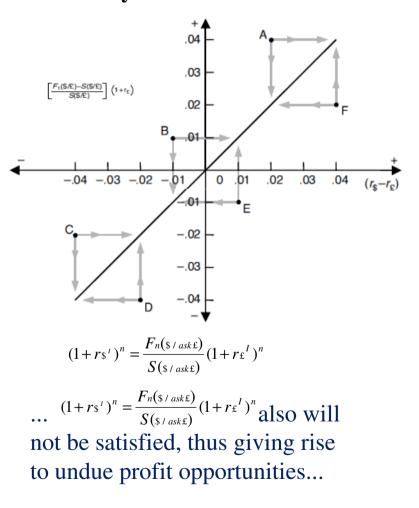

...and this will hardly ever occur in practice (Could you explain why?)

To sum up II

One-way transactions

To sum up III

... for instance, if $(1+rs^{T})^{n} > \frac{F_{n}(s/ask t)}{S(s/ask t)}(1+rt^{T})^{n}$, nobody would invest in a t-

denominated deposit (as market players would rather put their money in a \$-denominated investment)

This would gradually drive $r_{s}^{I} \downarrow$ and $r_{f}^{I} \uparrow$, until equilibrium is restored again and arbitrage opportunities are completely reabsorbed (No Free Lunch principle)

Transaction costs do <u>not</u> bring about profitable arbitrage opportunities

How to construct synthetic securities with spot and forward contracts + borrowing and lending

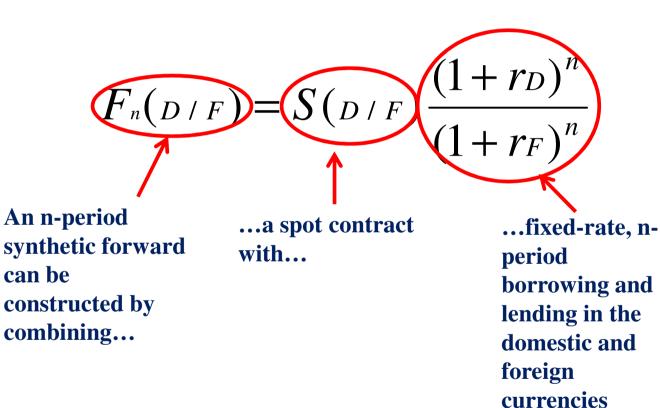

The CIRP implies

$$(1+r_D)^n = \frac{F_n(D/F)}{S(D/F)}(1+r_F)^n$$

Rearranging the terms

$$F_n(D/F) = S(D/F) \frac{(1+r_D)^n}{(1+r_F)^n}$$

32

respectively.

n(D / F) $(1 + r_F)$ $(1 + r_D)$ $\int (D / F)$

A synthetic domestic currencydenominated security can be obtained by combining...

...a foreign currencydenominated security with...

...a forward/spot swap.

Some lessons to learn

The **CIRP** is useful:

- 1.when trying to understand the direction of K movements \rightarrow towards the currency with higher covered yield;
- 2. to **build/replicate a financial contract**;
- 3. to hedge a financial position

To put it into practice I

Consider the following: Spot rate: Currency₁ 0.64/Currency₂

- $r_{1y_Currency1} = 5\%$ $r_{1y_Currency2} = 9\%$
- 1. Calculate the theoretical price of a one year forward contract.
- 2. What would you do if the forward price was quoted at Currency₁ 0.65/Currency₂ in the market place? Where would you borrow? Lend? Calculate the gain on a Currency₁ 100 million arbitrage transaction.
- 3. What would you do if the future price was quoted at $Currency_1 \ 0.60/Currency_2$ in the market place? Where would you borrow? Lend? Calculate the gain on a Currency_100 million arbitrage transaction.

The following exchange rates and one-year interest rates exist.

	BID	ASK
S ^{A/B}	1.52	1.63
F ^{1A/B}	1.42	1.53

	Deposit	Loan
r ^A	4%	9%
r ^B	5%	10%

You have 100 A to invest for 1 year. Would you benefit from engaging in covered interest arbitrage?
